

Upgrade or Replacement Options for SCUBA-2

Upgrade or Replace SCUBA-2

- ▶ Upgrades to the instrument that increase the mapping speed by 5 to 10 times, while significantly improving the ability to map faint extended structure would realise the full potential of SCUBA-2.
 - ▶ On the other hand, a replacement instrument might be similar cost and a less risky way to achieve the same results as an upgraded SCUBA-2, while SCUBA-2 itself continues uninterrupted on the telescope.
 - ▶ Or we could design and build a new instrument that pushes the boundaries again.
 - ▶ **The key: is to understand the needs of our uses and to develop an updated science case.**
-

The Factors for the Science Case

- ▶ Mapping speed
 - ▶ Improved / faster polarization maps
 - ▶ Better functional scanning FTS
 - ▶ Enhanced map making of extended emission
-
- ▶ Or are there other capabilities and features that users of JCMT would want in a continuum instrument such as
 - ▶ Multi-chroic detectors or on-wafer spectrometers
-

Upgrade SCUBA-2

- Reuse the SCUBA-2 cryostat, cold optics and cryogenics
- Reduce stray light / excess optical power on the arrays
- Replace the detector arrays or possibly the focal plane units or 1K box

The available field of view (at the Naysmyth) 8 x 8 arcmin, is used optimally – To get a larger field of view, requires moving to the cabin or a radical solution using new relay mirrors from the cabin

Reduce stray light/excess power

There have been significant improvements in the Cardiff filter design and manufacture, since the SCUBA-2 filters were designed and made

Proposing to remodel and then re-design and install new filters from the window to the 4K

Detector arrays

TES vs KID

- Both can achieve the required specs to upgrade SCUBA-2
 - Neither are off the shelf solutions
 - TES are more mature and have advanced since SCUBA-2
 - SQUID MUX has improved
 - lower power
 - more uniformity
 - less magnetic pickup
 - higher muxing factors
 - Know how to make good absorber and/or couple to TES
 - KID arrays are potentially simpler to fabricate
 - KID arrays don't require a SQUID MUX
 - The cold electronics for KIDs is an amplifier per 1000/2000 pixels
 - For TES arrays, the cold electronics is a SSA per 40 pixels
 - KID arrays are far less sensitive to thermal fluctuations
-

Engineering requirements For KID arrays

KID array development work for SCUBA-2

- Pixel design
- Choice of materials [Al, TiN]
- Choice of frequency of operation
- Coupling to radiation
- Testing and optimisation

AMKID

Next gen BLASTpol

MAKO

Exploratory work

Meeting in Cardiff:

Agreed to remodel/redesign the fillers.

Plan to swap in the summer (4-5 weeks down time)

- ▶ Simon Doyle (Cardiff) – offered to investigate designs and possibly make test pixels (already has funding).
 - ▶ In contact with groups at NIST Boulder and Stanford that are developing BLASTpol KID arrays.
 - ▶ Cardiff also have rectangular feed horn arrays developed for KIDCAM
-

Options for new arrays

- ▶ TES new 32 x 40 sub-arrays (most likely based on GSFC BUG architecture)
 - ▶ Larger TES arrays 40 x 40 (increase pixel count by factor of ~ 2) using larger 6 inch wafer. So far only NIST has this process worked out (making Advanced ACTPol detectors)
 - ▶ **KID arrays at least 40 x 40 sub-arrays**
 - ▶ [could move 450 to $F\lambda/2$ spacing - 80 x 80 sub-arrays]
 - ▶ Horn coupled KID arrays with $2F\lambda$ spacing
 - ▶ (See Griffin, Bock, Gear 2002)
 - ▶ **Dual-Polarisation sensitive KID array (BLASTpol pixel)**
 - ▶ 2 KIDs per pixel
-

New arrays

- ▶ Any new TES array will not be a copy of the existing SCUBA-2 array
 - ▶ Therefore cold electronics, wiring and heater (likely no heaters) will need to be redesigned.
 - ▶ This is particularly the case for larger TES arrays
 - ▶ We have not done a full costing but we are sure that we could put KID arrays in SCUBA-2 for \$1-\$2 million.
 - ▶ Success of new arrays contingent in improving sensitivity AND reducing the excess optical power.
 - ▶ KID arrays will be relatively immune to the temperature oscillations from the existing dilution fridge.
-

Potential gains in mapping speeds

- ▶ Mapping speed scales with number of pixels and sensitivity²
 - ▶ 40 x 40 sub-arrays (with dark NEP $3 \times 10^{-17} \text{ W/Hz}^{0.5}$)
 - ▶ Gains in mapping speed $\sim 9x$
 - ▶ (assuming 90% yield and successful reduction of excess optical power)
-

Replacement Instrument

- ▶ To do better than an upgraded SCUBA-2 (in mapping speeds) – need bigger field of view.
 - ▶ “Small” instrument in cabin with 15 arcmin field of view, using KID arrays 100,000 pixels – 20,000 at 850um could have 30x mapping speeds.
 - ▶ Baseline: Compact instrument, 3He or mini DR with Pulse tube cooler. Good control of stray light.
 - ▶ Would require significant work to the telescope/cabin structure.
-
